

Python Programming

Session Objective

To understand the basic concepts of Python,

- 🐍 Python and its Feature
- 🐍 History of the Python
- 🐍 Writing and Running First program
- 🐍 Keywords & Identifiers
- 🐍 Variables & Operators
- 🐍 Data Types
 - Numeric
 - Sequence
 - Boolean
 - Mapping

Python Features

What is Python?

- ❖ **Python** is an interpreted, interactive, object-oriented language.
- ❖ It supports the use of modules and packages
- ❖ It is extremely used in the field of Rapid Application Development

Why to learn Python?

Interpreted :

Python is processed at runtime by the interpreter.
Python codes need not be compiled before execution.
This is like PERL and PHP.

Interactive :

Python prompt can interact with the interpreter directly to write programs.

Object-Oriented :

Python supports Object-Oriented technique of programming that encapsulates code within objects.

Beginner's Language :

Python supports the development of a wide range of applications from simple text processing to browsers to games.

Standard library :

Python's library is very portable and cross-platform compatible on UNIX, Windows, and Macintosh.

GUI Programming :

Python supports GUI applications that can be created and ported to many system calls, libraries and windows systems, such as Windows MFC, Macintosh, and the X Window system of Unix.

Scalable :

Python provides a better structure and support for large programs than shell scripting.

Portable :

Python can run on a wide variety of hardware platforms and has the same interface on all platforms.

Extendable :

Low-level modules can be added to the Python interpreter.

These modules enable programmers to add to or customize their tools to be more efficient.

Databases :

Python provides interfaces to all major commercial databases.

History of Python

- Python was developed by **Guido van Rossum** in 1980
- Python is derived from ABC, Modula-3, C, C++, Algol-68, Smalltalk, and Unix shell and other scripting languages.

Python Version	Features
Python 1.0	Lambda, map, filter, and reduce.
Python 2.0	List comprehensions, garbage collection systems.
Python 3.0 - "Py3K"	Designed to rectify the fundamental flaw of the language.

Python Applications

Famous Companies that uses PYTHON

Python First Application

General Editors and IDEs with Python Support

- ✓ Eclipse + PyDev
- ✓ Sublime Text
- ✓ Atom
- ✓ GNU Emacs
- ✓ Vi / Vim
- ✓ Visual Studio
- ✓ Visual Studio Code

Python-Specific Editors and IDEs

- PyCharm
- Spyder
- Thonny

First Python Program

Python provides different ways to run a program:

- 🐍 Using Interactive interpreter prompt
- 🐍 Using a script file
- 🐍 Using IDE

Write your first python Program

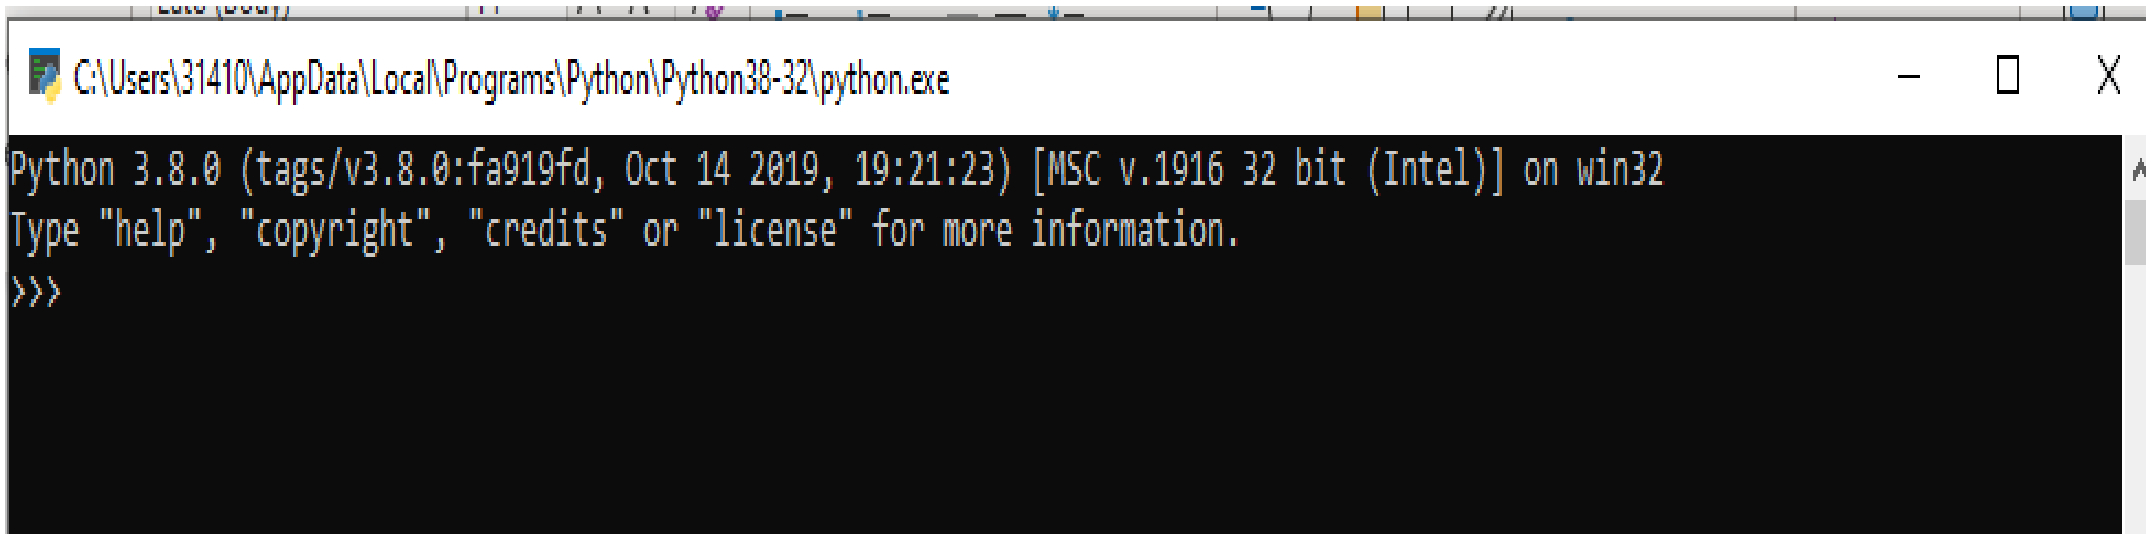

```
print "Hello World"
```

Interactive Mode:

 To open in interactive mode, open the terminal (or command prompt),

STEP1:

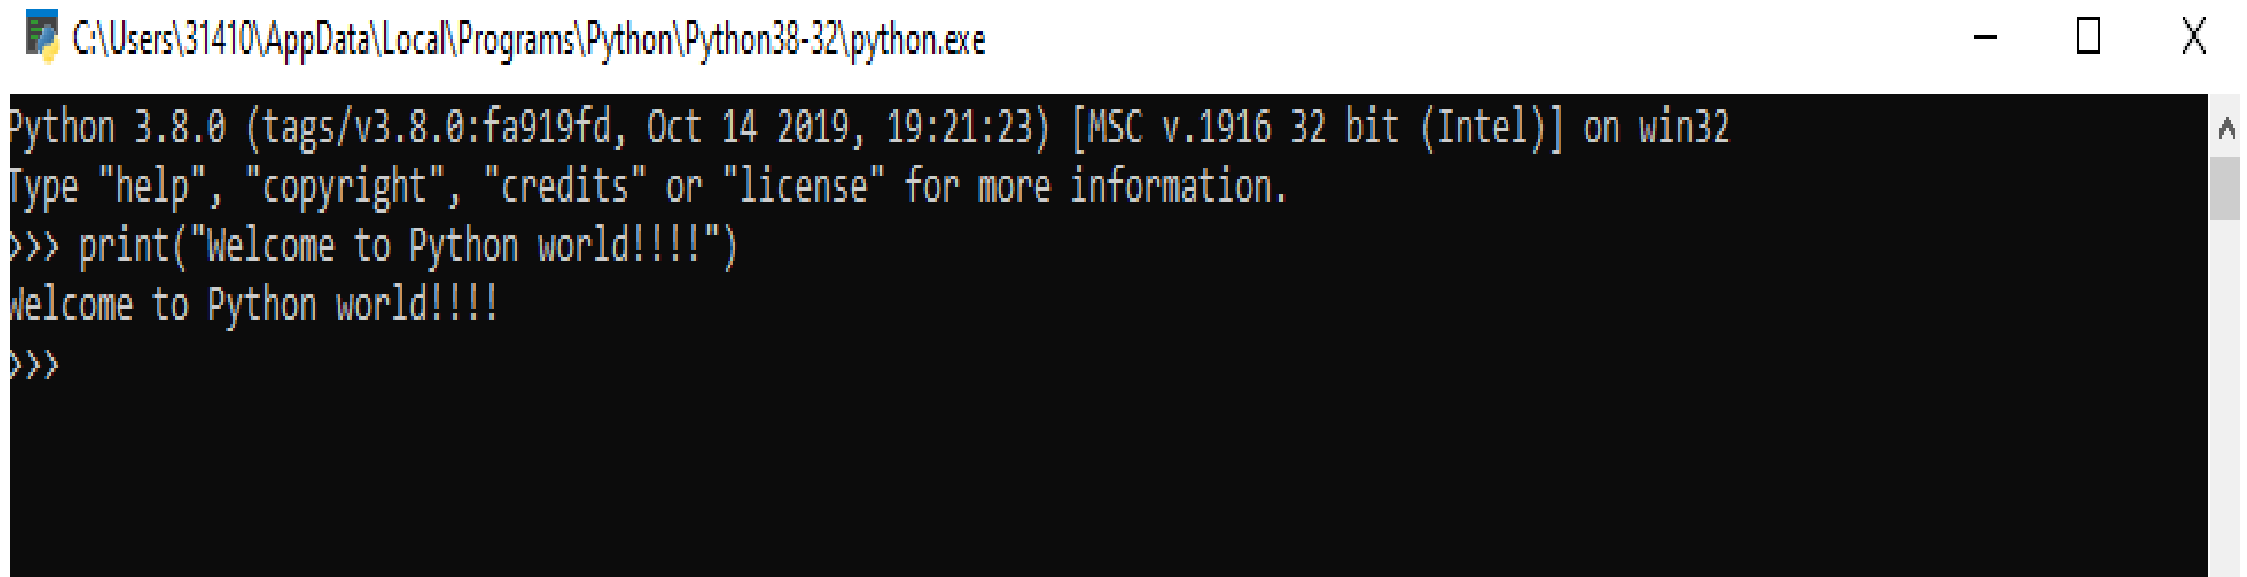

```
C:\Users\31410\AppData\Local\Programs\Python\Python38-32\python.exe

Python 3.8.0 (tags/v3.8.0:fa919fd, Oct 14 2019, 19:21:23) [MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license" for more information.
>>>
```

STEP 2:

Write the Python code for execution,

A screenshot of a Windows command prompt window. The title bar shows the file path 'C:\Users\31410\AppData\Local\Programs\Python\Python38-32\python.exe'. The window has standard Windows window controls (minimize, maximize, close). The command prompt shows the Python 3.8.0 shell with the following text:

```
Python 3.8.0 (tags/v3.8.0:fa919fd, Oct 14 2019, 19:21:23) [MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license" for more information.
>>> print("Welcome to Python world!!!!")
Welcome to Python world!!!!
>>>
```

Script file:

- ✓ Interpreter prompt is good to run the individual statements of the code.
- ✓ To execute block of statements, write the code into a file which can be executed later.
- ✓ Open an editor like notepad, create a file named Welcome.py (Python used .py extension) and write the following code in it.

STEP 1:

Create a file “Welcome.py”

STEP 2:

Enter the following code

```
Print(“Welcome to Python World!!!!!!!!!!!!!!”)
```

STEP 3:

Run the following command on the terminal.

python Welcome.py

A screenshot of a Windows Command Prompt window titled "Select Command Prompt". The window shows the following text: "Microsoft Windows [Version 10.0.18362.900]", "(c) 2019 Microsoft Corporation. All rights reserved.", "C:\Users\31410>cd Desktop", "C:\Users\31410\Desktop>python Welcome.py", "Welcome to Python World!!!!!!", and "C:\Users\31410\Desktop>". A white cursor is visible at the end of the last line.

```
C:\Users\31410>cd Desktop
C:\Users\31410\Desktop>python Welcome.py
Welcome to Python World!!!!!!
C:\Users\31410\Desktop>
```

PyCharm IDE

PyCharm is specially used for Python language. It is used for intelligent code completion, on-the-fly error checking and quick-fixes, easy project navigation, and much more.

STEP 1:

File -> New Project->(Enter the project name) -> click Create button

STEP 2:

Right click the Project -> New-> Python file->(Enter the name of the file)

STEP 3:

Enter the Code in the workspace

STEP 4:

To Execute the code
Run-> Run>Welcome'

First Python Program

Contd...

A screenshot of the PyCharm IDE interface. The top menu bar includes File, Edit, View, Navigate, Code, Refactor, Run, Tools, VCS, Window, and Help. The title bar shows 'SampleProject [C:\Users\31410\PycharmProjects\SampleProject] - ...\Welcome.py - PyCharm'. The left sidebar shows the Project view with 'SampleProject' expanded, revealing a 'venv' directory (library root) and a 'Welcome.py' file. The main editor window shows the code for 'Welcome.py' with a single line: `print("Welcome to Python World!!!!!!")`. The bottom panel shows the Run view with a single run configuration named 'Welcome'. The output console displays the command `C:\Users\31410\PycharmProjects\SampleProject\venv\Scripts\python.exe C:/Users/31410/PycharmProjects/SampleProject/Welcome.py`, the output `Welcome to Python World!!!!!!`, and the message `Process finished with exit code 0`.

Keywords, Identifiers, Variables & Operators

Keywords in Python

- ❑ Each keyword has a special meaning and a specific operation.
- ❑ These keywords can't be used as a variable.
- ❑ Python Keywords are special reserved words that gives special meaning to the compiler/interpreter.

Identifiers in Python

- An identifier is a name given to an entity.

Best Practices for Python Identifiers

- 🐍 Class names should start with a capital letter and all the other identifiers should start with a lowercase letter.
- 🐍 Begin private identifiers with an underscore (_).
- 🐍 Use double underscores (__) around the names of magic methods and don't use them anywhere else. Python built-in magic methods already use this notation.
For example: `__init__` , `__len__` .

- 🐍 Always prefer using names longer than one character. `index=1` is better than `i=1`
- 🐍 To combine words in an identifier, you should use underscore(_).
For example: `get_user_details`.
- 🐍 Use camel case for naming the variables.
For example: `fullName`, `getAddress`, `testModeOn`, etc.

Python Variables

- ❖ Python variables are containers for storing data values
- ❖ Python is Dynamically-Typed
- ❖ Data type is not required for variable declaration. This is decided by the interpreter at runtime.

Operators in Python

Python Operators

Arithmetic Operators

Relational Operators

Assignment Operators

Logical Operators

Bitwise Operators

Membership Operators

Identity Operators

Python Arithmetic Operators

Python Comparison Operators

Comments in Python

Single line Comment

- To apply the comment in the code use the hash(#) at the beginning of the statement or code.

```
# Single line comment
```

Multi line Comment

- To apply multiline comment use hash(#) at the beginning of every line.

```
# First line of the comment  
# Second line of the comment  
# Third line of the comment
```

Docstring Comments

- The docstring comment is mostly used in the module, function, class or method.

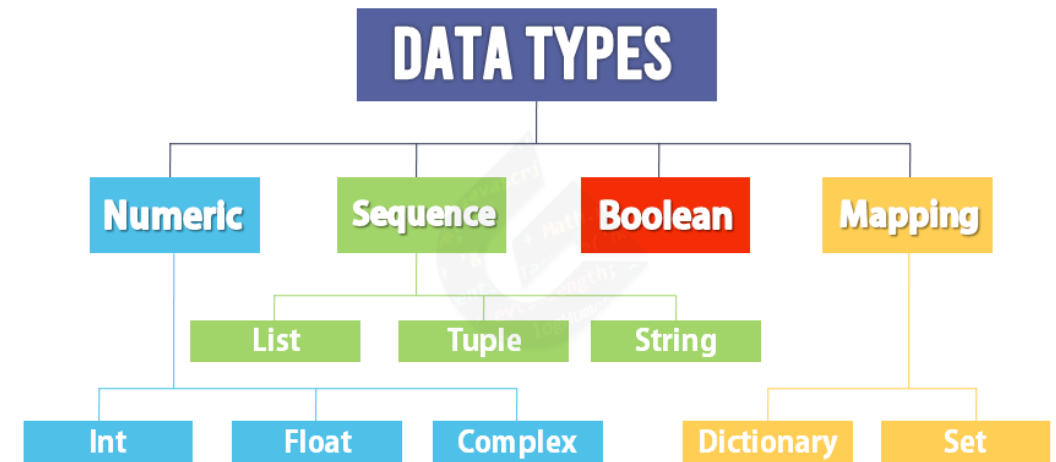

```
def intro():  
    """  
    This function prints Employee details  
    """  
    print("Employee details")  
  
intro()
```

Data Types in Python

Data Types in Python

NUMERIC TYPE:

- Number stores numeric values.
- The integer, float, and complex values belong to a Python Numbers data-type.
- `type()` function is used to know the data-type of the variable.
- `isinstance()` function is used to check an object belongs to a particular class.

Numeric Example

```
>>> num=2.5
>>> type(num)
```

Output:
<class 'float'>

```
>>> num1=55
>>> type(num1)
```

Output:
<class 'int'>

Complex:

```
>>> result=2+3j
```

```
>>> result
```

Output:
(2+3j)

```
>>> type(result)
```

Output:
<class 'complex'>

SEQUENCE TYPE

String:

- The string can be defined as the sequence of characters represented in the quotation marks.
- Python string can be single, double, or triple quotes.
- The operator + is used to concatenate two strings.
- operator * is known as a repetition operator.

String Example

```
>>>name="Python"
```

```
>>>name+" rocks"
```

Output:

Python rocks

```
>>> "python " *2
```

Output:

'python python '

LIST:

- List is an ordered sequence of items.
- All the items in a list do not need to be of the same type.
- Items separated by commas are enclosed within brackets [].

```
>>> num=[22,33,44,55]
```

```
>>>num
```

Output:

```
[22,33,44,55]
```

```
>>>num[0]
```

Output:

```
22
```

[can retrieve with specific index]

List Example

```
Project=["BI","ATM","BFS"]  
Employee = [12,'vimala',3333]  
value=[Employee,Project]
```

Output:

```
[[12,'vimala',3333], ["BI","ATM","BFS"]]
```

List is Mutable = can change the values

TUPLE:

- Tuple is an ordered sequence of items same as a list. The only difference is that tuples are immutable. Tuples once created cannot be modified.
- Tuples are used to write-protect data and are usually faster than lists as they cannot change dynamically.
- It is defined within parentheses () where items are separated by commas.

```
>>> tup=(12,33,44,55)  
>>> tup
```

Output:
(12, 33, 44, 55)

MAPPING

SET:

- Set is an unordered collection of unique items.
- Set is defined by values separated by comma inside braces { }.
- Items in a set are not ordered.

```
>>> s={21,71,1,51}
```

```
>>> s
```

Output

```
{1, 51, 21, 71}
```

```
>>> s={3,4, 5,3,4}
```

```
>>> s
```

Output:

```
{3, 4, 5} [does not give the repeated value]
```

DICTIONARY:

- Dictionary is an unordered collection of key-value pairs.
- It is generally used when we have a huge amount of data.
- Dictionaries are optimized for retrieving data. Key is used to retrieve the value.
- In Python, dictionaries are defined within braces {} with each item being a pair in the form key:value.
- Key and value can be of any type.

Difference between List and Dictionary

List	Dictionary
Elements are in order	Elements are unordered
List contains data types like Integers, Strings, as well as Objects.	It is used to store data values like a map
They are accessed via numeric indices.	Elements are accessed using key values

BOOLEAN

```
>>> a=34
>>> b=22
>>> comp=a>b
>>> comp
```

Output:
True

```
>>> a<b
Output:
False
```

```
>>> type(comp)
Output:
<class 'bool'>
```

1. Is python a case sensitive language?
2. What data type is used to store values in terms of key and value?
3. What will be the output of the following Python statement?

```
>>>"You"+"rock"
```
4. Give 2 example for Magic methods in Python?
5. Which type is not ordered and does not allow duplicates?

Think & Answer

1. True
2. Dictionary
3. Yourock
4. __init__, __add__, __len__
5. Set

Thank you
